"Optoelectronic module with integrated loop-back capability"

\* \* \*

The present invention relates to optical telecommunication systems and, more specifically, is related with monitoring performance of such systems.

In optical telecommunication systems, bit error ratio (BER) and uptime are important measures of the quality of the system. For example, some system elements are required to have uptimes of 99.995% or 99.999%, including both planned and unplanned downtime.

An important way of ensuring high uptime values is to continually monitor the performance of the system elements to locate faults, allowing them to be put right quickly, and to identify defects before they become faults allowing them to be corrected without any unplanned downtime.

A way of monitoring the performance of system elements is by loop-back testing. Such a testing technique provides for a signal destined for a remote location to be instead directed to a nearby receiver; in the case of a transceiver, the signal launched from its transmitter may be returned to its receiver. Often the signal is attenuated to simulate the losses in the optical telecommunication system.

Generally, loop-back testing requires a technician to physically remove the connectors of the optical telecommunication system and replace them with a so-called patchcord, or the connectors of a variable optical attenuator (VOA). The system can then be tested in the loop-back condition and finally the patchcord, or the connectors of the VOA, can be removed and the system connectors replaced.

Figure 1 shows a transceiver module including transmitter and receiver sub-modules T and R, as well

30020606 EP

as the associated control electronics E integrated into a housing H to transmit digital input signals I and receive digital output signals O via an optical communication system connected to the housing H via a transmitter connector C1 and a receiver connector C2.

This arrangement is thoroughly conventional in the art and does not require to be described in detail herein.

Figure 1 shows a typical loop-back testing condition for the system in question where the optical telecommunication system has been disconnected and replaced by a patchcord arranged to receive light from the transmitter T via the connector C1 and re-direct it to the receiver R via the connector C2.

The patchcord typically includes a length of an optical fibre F (currently designated loop-back fibre), possibly including a variable optical attenuator or VOA that attenuates the light. Resorting to such an arrangement requires a technician to physically remove the connectors of the optical telecommunication system and replace them with the patchcord. The system can then be tested in the loop-back condition and finally the patchcord can be removed and the system connectors replaced.

This is a laborious and time-consuming process.

The need is therefore felt for solutions overcoming the disadvantages of the prior art considered in the foregoing.

According to the present invention such an object is achieved by means of an optoelectronic integrated loop-back arrangement as called for in the claims that follow.

The module of the invention includes, as an integral part thereof, a selectively activatable loop-back arrangement. Preferably, the loop-back arrangement

includes one or more internal optical switches adapted to connect the transmitter and receiver included in the module to the optical telecommunication system, in which case the transceiver module functions as a standard transceiver module. Alternatively, the loop-back arrangement can connect the transmitter to the receiver to allow loop-back testing. The loop-back arrangement can be controlled remotely over the digital interface to the transceiver. The intervention of a technician is thus no longer required and loop-back testing can be performed in a quick and cheap manner.

The invention will now be described, by way of example only, with reference to the annexed drawings, wherein:

- Figure 1, relating to the prior art, has been already described in the foregoing,

- Figures 2a and 2b show the general arrangement of a loop-back testing facility according to the invention with reference to current operation of the telecommunication system and to the testing phase, respectively,

- Figures 3a and 3b illustrate in greater detail an optoelectronic circuit layout adapted for use in certain embodiments of the invention,

- Figures 4 to 6 refer to various further alternative embodiments of the invention.

Elements/parts identical or equivalent to those already referred to in connection with figure 1 have been indicated throughout figures 2 to 6 using the same references, thus making it unnecessary to identify and describe those elements/parts again.

Figures 2a and 2b show schematically a transceiver module with integrated optical switches S1 and S2. The switches S1 and S2, preferably together with a length of an optical waveguide OW extending between the

switches S1 and S2, are adapted to selectively define a loop-back circuit connecting the transmitter T to the receiver R.

Specifically, in the condition shown in figure 2a,  
5 the optical switches S1 and S2 are set to allow propagation of optical radiation:

- from the transmitter T into the optical telecommunication system via the connector C1, and
- from the optical communication system into the  
10 receiver R via connector C2.

In the operating condition shown in figure 2b, the optical radiation from transmitter T, instead of being directed towards connector C1, is switched via the optical switch S1 over the optical waveguide OW and on  
15 into the receiver R via the optical switch S2.

Figures 3a and 3b, that essentially correspond to figure 2a and 2b, respectively, show in more detail a transceiver module with integrated optical switches S1, S2 and a loop-back circuit associated therewith.

20 In this embodiment, light from the transmitter T (typically a laser source) is collimated via an optical system such as a lens V1 to be then propagated through an (optional) isolator IS arranged at the upstream of the loop-back arrangement and then focussed through a further lens V2 into the connector C1 to be propagated  
25 into the optical communication system (not shown).

Similarly, light received from the optical telecommunication system via the connector C2 is collimated and then focussed via further lenses V3 and  
30 a lens V4 into the receiver R (this is typically an opto-electrical converter such as a photodiode or a phototransistor).

In a first embodiment, the optical switches essentially comprise mirrors M1 and M2 adapted to be  
35 selectively positioned in the transmitter collimated

beam and the receiver collimated beam to reflect the light from the transmitter laser T to the receiver photodetector R providing a loop-back mode.

5 An optional, preferably variable optical attenuator VOA is positioned between the mirrors M1 and M2 to attenuate the light.

Propagation of light from the mirror M1 to the mirror M2 can be unguided (that is not through an optical waveguide proper), the variable optical  
10 attenuator VOA being in any case arranged to be interposed in the optical path from mirror M1 to mirror M2.

It will be appreciated that the representation of the mirrors M1 and M2 in shadow lines in figure 3a may  
15 be purely notional in that - in the operating condition shown therein - the mirrors M1 and M2 may in fact be moved away from the propagation path between the lenses V1 and V2 and the propagation path between lens V3 and lens V4.

20 Any mechanical actuator known in the art can be utilised for moving the mirrors M1 and M2 between a first "passive" i.e. non-reflecting condition shown in figure 3a and a second "active" i.e. reflecting condition shown in figure 3b where the mirror M1  
25 actually prevents radiation from laser source T from propagating towards the lens V2 and the connector C1.

In the operating conditions shown in figure 3b such radiation is reflected from the mirror M1 towards the variable optical attenuator VOA (if present) and  
30 then towards the mirror M2 to be then reflected back towards the photodetector R through the lens V4.

The art of micro-machining provides several mechanisms adapted for the purpose indicated, thus making it unnecessary to provide a detailed discussion  
35 herein. Specifically, mechanisms that utilize sliding

actuators are well known to those of skill in the art of micro machining. In addition, the mirrors M1, M2 can be positioned on "flip-up" or rotary actuators.

For a more detailed discussion of these  
5 techniques, reference may be had to Ming C. Wu, "Micromachining for optical and optoelectronic Systems", IEEE 85, no. 11, pp 1833-1856, 1997.

Those of skill in the art will also appreciate that alternative embodiments of either or both mirrors  
10 M1 and M2 may not provide for such mirrors being rendered selectively movable between a "passive" position where the mirror is disengaged (i.e. displaced) with respect to the optical path of propagation from the source T and the receiver R (e.g.  
15 figure 3a) and an "active" position where the mirror does intercept such an optical path (e.g. the position shown in figure 3b). For instance, either or both of the mirrors M1 and M2 can be implemented in the form of mirrors adapted to be selectively switched between a  
20 first "passive" state where they do not exhibit any appreciable reflective effect (thus permitting optical radiation from the source T and/or towards the receiver R to freely propagate therethrough) and a second "active" state where the mirror exhibits a reflective  
25 surface adapted to reflect radiation from the transmitter T towards the receiver R. Selectively activatable mirrors of this kind are known in the art as witnessed e.g. by Hikmet, R.A.M., Kemperman, H., Electrically switchable mirrors and optical components  
30 made from liquid-crystal gels, *Nature*, Volume 392, Issue 6675, 1998, Pages 476-479. The general layout shown in figure 3b lends itself to another embodiment of the invention, wherein the mirrors M1 and M2 can be realised in the form of fixed,  
35 partially silvered mirrors that allow e.g. 96% straight

through coupling and 4% reflection, that is mirrors having a high straight through coupling/reflection ratio. By "high", a ratio is meant herein of the order of e.g. 20 or more.

5        Having regard to the straight through coupling value indicated, the main signal paths from the transmitter T to the connector C1 and from the connector C2 to the receiver R are little impaired by the presence of the mirrors M1 and M2.

10        Even though relatively minor (e.g. 4% reflection) the reflection at the mirror M1 causes a portion of the radiation generated by the transmitter T to be reflected towards the variable optical attenuator VOA. Any radiation passing through the variable optical  
15        attenuator may thus be directed towards the mirror M2. Again, even though relatively minor (e.g. 4% reflection), the reflection at the mirror M2 causes a portion of the radiation from the variable optical attenuator VOA to be reflected by the mirror M2 towards  
20        the receiver R.

      A loop-back path is thus established from the transmitter T to the receiver R which has a loss of .002 or 26dB (mirrors S1 and S2), plus the loss of the variable optical attenuator VOA. This loss can be  
25        selectively adjusted to be high (say >25 dB) under normal operation and low (say <2dB) under loop back test operation.

      When the loss of the variable optical attenuator VOA is adjusted to be high, the overall loss of the  
30        loop-back path is very high (e.g. in the excess of 50 dB), so that no appreciable level of optical radiation from the transmitter T reaches the receiver R.

      Conversely, when the loss of the variable optical attenuator VOA is adjusted to be low, the overall loss  
35        of the loop-back path is in the range of 28 dB. Under

these conditions, a level of optical radiation from the transmitter T reaches the receiver R that is high enough to enable loop-back testing to be carried out in a thoroughly satisfactory manner by simply ensuring  
5 that no interfering optical radiation from outside reaches the receiver R through the connector C2 while testing is being performed.

This technique, based on the recognition that the path loss capability of a transceiver might typically  
10 be of the order of 30 dB from the transmitter T to the receiver R, avoids moving parts; only the VOA's attenuation changes which could be e.g. a liquid crystal cell.

Figure 4 shows a further alternative embodiment  
15 where, instead of being interposed between the mirrors M1 and M2 as shown in figure 3, the variable optical attenuator VOA is arranged in the propagation path between the transmitter T and the mirror M1. This is preferably achieved by interposing the variable optical  
20 attenuator VOA between the isolator IS (or the lens V1) and the mirror M1.

The arrangement shown in figure 4 has the advantage that the variable optical attenuator VOA can control the light intensity both when propagated into  
25 the optical telecommunication system as well as in the loop-back mode.

Figure 5 shows another alternative embodiment wherein the transmitter or source T plus the connector C1, on the one hand, and the connector C2 plus the  
30 receiver R, on the other hand, form two rectilinear propagation paths arranged in a cross-wise pattern. The two propagation paths thus defined cross at a position where a single reflective mirror M12 may be located by being selectively displaced between a "passive" and an  
35 "active" position. Alternatively, the mirror M12 may be

of the kind adapted to be alternatively and selectively rendered transparent and reflective as discussed in the foregoing.

When the mirror M12 is in the "passive" state,  
5 optical radiation generated from the laser source T is propagated through the lens V1, the isolator IS and the variable optical attenuator VOA, to traverse the mirror M12 and reach the lens V3 to be focussed into the connector C1. Similarly, incoming radiation from the  
10 connector C2 passes through the lens V3 as well as the mirror M12 to reach the lens V4 to be focussed onto the photodetector R.

When the mirror M12 is in the "active" reflective state, optical radiation from the laser source T,  
15 instead of being propagated through the mirror towards the lens V2 and the connector C1, is reflected by the mirror M12 towards the lens V4 and the photodetector R to complete the loop-back path.

Figure 6 shows still another embodiment where the  
20 switches S1 and S2 as well as the loop-back optical waveguide OW are integrated in a planar lightwave circuit (PLC).

PLCs are well known and are described e.g. in "Silica-based single-mode waveguides on silicon and  
25 their application to guided-wave optical interferometers", Takato, N., Jinguji, K., Yasu, M., Toba, H., Kawachi, M; Journal of Lightwave Technology, Volume 6 Issue 6, June 1988, Pages 1003-1010; "Recent progress on silica-based thermooptic switches 1999,  
30 Pages 485-486; "Silica-based planar lightwave circuits"; Himeno, A., Kato, K., Miya, T; IEEE Journal on Selected Topics in Quantum Electronics; Volume 4 Issue 6; Nov.-Dec. 1998; Pages 913-924.

Of course, without prejudice to the basic  
35 principle of the invention, the details of construction

and the embodiments may widely vary with respect to what has been described and illustrated purely by way of example, without departing from the scope of the present invention. Also, it will be appreciated that, according to the current meaning in the art, designations such as "optical", "light" and so on are in no way restricted to the sole domain of visible light radiation. These designations do in fact apply to the whole of the wavelength domains adapted for use in optical communications, including e.g. the UV and IR domains.

30020606 EP

CLAIMS

1. An optoelectronic module, including:

- an optical radiation source (T) having associated an output transmission path (V1, V2, C1) for an output optical radiation generated by said source (T),

- an optical radiation detector (R) having associated an input transmission path (C2, V3, V4) for an input optical radiation to be detected by said detector (R),

characterised in that the module includes, as an integral part thereof, a loop-back arrangement (M1, M2; M12; VOA; OW) selectively activatable to cause said output optical radiation generated by said source (T) to at least partly propagate from said output transmission path (V1) towards said input transmission path (V4), whereby said optical radiation generated by said source (T) is directed towards said optical detector (R) to be detected thereby.

2. The module of claim 1, characterised in that said loop-back arrangement includes at least one loop-back element (M1, M2; M12) adapted to have a surface reflectively interposed in at least one of said output transmission path (V1, V2) and said input transmission path (V3, V4) to reflect optical radiation generated by said source (T) towards said optical detector (R).

3. The module of claim 2, characterised in that said at least one loop-back element includes a mirror (M1, M2; M12) having a reflective surface adapted to be selectively moved between a first position, wherein said reflective surface is located away from said at least one of said output transmission path (V1, V2) and said input transmission path (V3, V4) and a second position wherein said reflective surface intercepts at

least one of said output transmission path (V1, V2) and said input transmission path (V3, V4).

4. The module of claim 2, characterised in that said at least one loop-back element includes a stationary mirror (M1, M2; M12) selectively switchable between a first condition, wherein said mirror (M1, M2; M12) is substantially transparent to optical radiation propagating therethrough and a second condition, wherein said mirror exhibits said surface reflectively interposed in at least one of said output transmission path (V1, V2) and said input transmission path (V3, V4).

5. The module of any claims 2 to 4, characterised in that said loop-back arrangement includes first (M1) and second (M2) loop-back elements, said first loop-back element (M1) adapted to have a first surface reflectively interposed in said output transmission path (V1, V2) to reflect optical radiation generated by said source (T) towards said second loop-back element (M2); said second loop-back element (M) adapted to have a second surface for reflectively receiving said optical radiation reflected by said first loop-back element (M1) and direct said reflected radiation towards said optical detector (R).

6. The module of any of the previous claims, characterised in that said loop-back arrangement includes an optical attenuator (VOA) arranged to be traversed by optical radiation propagating from said source (T) towards said optical detector (R).

7. The module of claims 5 and 6, characterised in that said optical attenuator (VOA) is interposed between said first (M1) and second (M2) loop-back elements.

8. The module of claim 6, characterised in that said optical attenuator (VOA) is a variable optical

attenuator adapted to be selectively switched between a first, high loss condition, wherein said variable optical attenuator (VOA) substantially prevents propagation of optical radiation from said source (T) towards said detector (R) and a second, low loss condition, wherein said variable optical attenuator (VOA) permits propagation of optical radiation from said source (T) towards said detector (R).

9. The module of claims 7 and 8, characterised in that said first (M1) and second (M2) loop-back elements are mirrors having a high straight through coupling/reflection ratio.

10. The module of claim 5 and claim 6, characterised in that said optical attenuator (VOA) is a variable optical attenuator interposed between said source (T) and said first loop-back element (M1).

11. The module of any of claims 2 to 6, characterised in that said optical radiation source (T) and said optical radiation detector (R) are arranged so that said output transmission path (V1, V2) and said input radiation path (V3, V4) intersect at a point of intersection and in that a single loop-back element (M12) is provided adapted to have said surface reflectively located substantially at said point of intersection.

12. The module of claim 6 and claim 11, characterised in that said variable optical attenuator (VOA) is interposed between said optical source (T) and said single loop-back element (M12).

13. The module of any of the previous claims, characterised in that said optical radiation source (T) has associated an optical isolator (IS) arranged at the upstream end of said loop-back arrangement.

14. The module of any of the previous claims, characterised in that said loop-back arrangement is in the form of a planar lightwave circuit (PLC).

---

30020606 EP

ABSTRACT

An optoelectronic module includes an optical radiation source (T) having associated an output transmission path (V1, V2, C1) for an output optical radiation generated by the source (T) as well as an optical radiation detector (R) having associated an input transmission path (C2, V3, V4) for an input optical radiation to be detected by said detector (R). The module includes, as an integral part thereof, a loop-back arrangement (M1, M2; M12; VOA; OW) selectively activatable to cause the output optical radiation generated by the source (T) to at least partly propagate from the output transmission path (V1) towards the input transmission path (V4), whereby the optical radiation generated by the source (T) is directed towards the optical detector (R) to be detected thereby.
